

# Flavour Structure in Baryon-Violating RPV SUSY

- Different  $\lambda''_{ijk}$  RPV couplings cause LSP decays to different quarks:

$$\tilde{\gamma}_1^0 \rightarrow q_1 q_2 q_3$$

- Identifying the dominant  $\lambda''$  gives insight into flavour physics!

- Use vertexing and non-isolated muons to statistically separate  $c$ - and  $b$ - from light quark jets.

- Ben Allanach  
Alan Barr  
Andy Parker  
Peter Richardson  
Bryan Webber

# R-Parity Violation

$$R_P = (-1)^{3B+L+2S}$$

+1 for SM particles  
-1 for SUSY particles

- Consequences of RPV
  - Decay of Lightest SUSY Particle (LSP)
  - Large couplings  $\Rightarrow$  single sparticle production.

- $\lambda_{ijk} L^i L^j E^k \Rightarrow \tilde{\chi}_1^0 \rightarrow \text{leptons}$
- $\lambda'_{ijk} L^i Q^j D^k \Rightarrow \tilde{\chi}_1^0 \rightarrow l \text{ or } u + \text{jets}$
- $\lambda''_{ijk} U^i D^j D^k \Rightarrow \tilde{\chi}_1^0 \rightarrow qqq$
- Hardest at LHC is  $\lambda''$  - no leptons, many jets!

# Test Models

- Our test model:  
mSUGRA parameters:

$$m_0 = 100 \text{ GeV}$$

$$m_{1/2} = 300 \text{ GeV}$$

$$A_0 = 300 \text{ GeV}$$

$$\tan\beta = 10$$

$$\mu > 0$$

$$\lambda''_{ijk} = 0.005$$

$$\tilde{\chi}_1^0 = 116.7 \text{ GeV}$$

$$\tilde{\chi}_2^0 = 211.9 \text{ GeV}$$

$$\tilde{q} \approx 600 - 700 \text{ GeV}$$

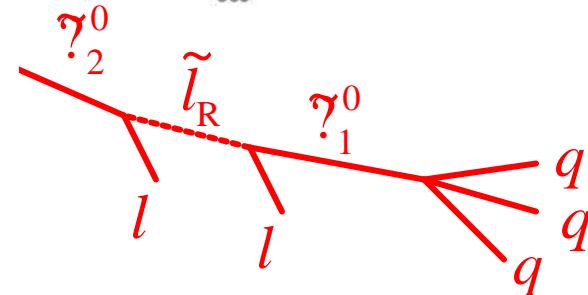

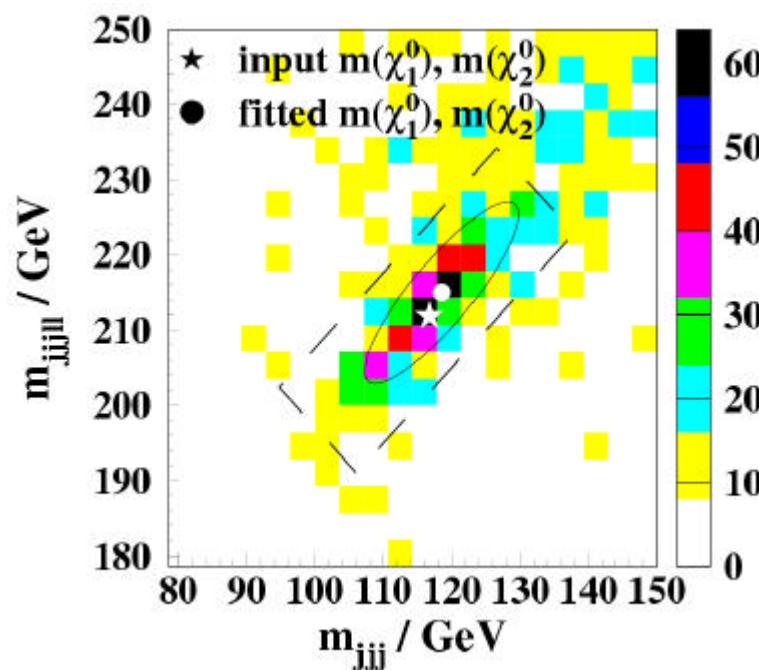

- Allowed  $\cancel{B}$  couplings:
- $\lambda''_{ijk}$  antisymmetric in  $j \leftrightarrow k$
- Do not consider  $\lambda''_{tjk}$  (long lived  $\tilde{\chi}_1^0$  must decay through virtual top quark)
- Couplings which can lead to decay inside the detector:

uds, udb, usb,  
cds, cbd, csb.

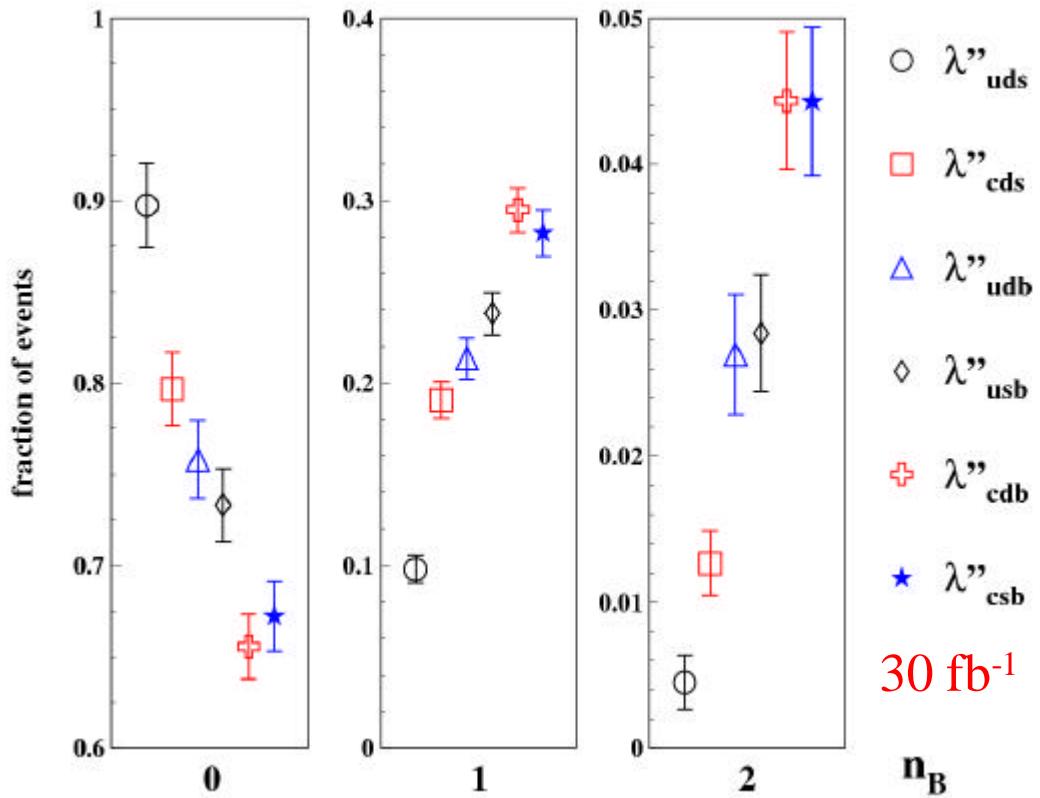

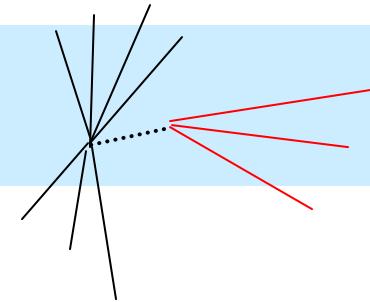

# Event Generation & Selection

- Herwig 6.2
- AtlfastF 2.50
- Selection of events by mass reconstruction  
(hep-ph/0102173)  
using  $\tilde{l}_R$  decay chain.
- Accept events within  $2\sigma$  of the  $\tilde{\gamma}_1^0 - \tilde{\gamma}_2^0$  mass peak.

# Vertex Tagging

Tagging Efficiency  
applied to Atlfast  
from full simulations:

b-jets 1 / 3.0

c-jets 1 / 22.9

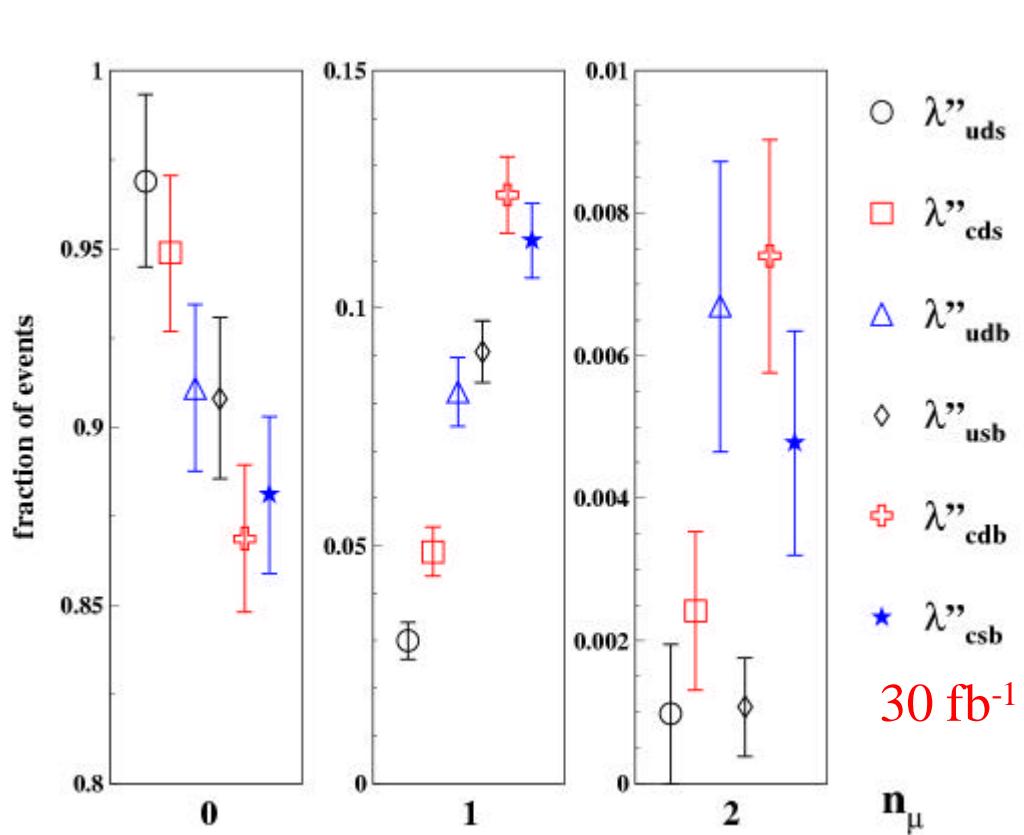

other jets 1 / 1400

( $p_T$  and  $\mathbf{h}$  dependent)

- Statistical separation of  $b$  and  $c$  from light quarks.
- Ambiguity between  $s$  and  $d$ .

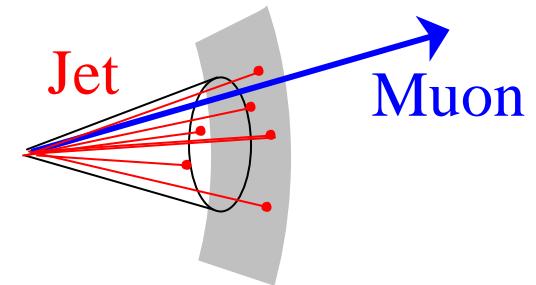

# Non-Isolated Muons

Muons are  
“non-isolated” if  
within jet cone.

Cone radius = 0.4

- Also provides discrimination.
- Still viable if decay is beyond Inner Detector

# Statistical Significance

$$\chi^2 = \sum_i \frac{(x_i - y_i)^2}{s_x^2 + s_y^2}$$

with  $x_i, y_i$  the fraction of events with  $i$  muons (or  $i$  vertex tags)

P < 1% not shown

All distinguished at  $3.5\sigma$ , except for an ambiguity d  $\leftrightarrow$  s

# Conclusions

- Can identify jets from  $\tilde{\chi}_1^0 \rightarrow q_1 q_2 q_3$
- Statistical separation of  $c$  and  $b$  from light quark jets.
- Remaining ambiguity from  $d \leftrightarrow s$
- Dominant coupling could be identified at  $> 3.5 \sigma$
